How to check every claim

Six Gemini specialists on one ClickHouse foundation. An orchestrator correlates them unprompted, on a schedule.

VERIFY IT WITHOUT CLONING ANYTHING

Two URLs, a browser, about thirty seconds.

https://the-backlot-203953305168.us-central1.run.app/
The Control Room console. The Watchtower panel in the sidebar is already populated on load — those findings were produced on a schedule. Nobody asked for them.

https://the-backlot-203953305168.us-central1.run.app/api/watch/findings
The same findings as raw JSON: the timestamp, the severity the orchestrator assigned itself, which specialists it consulted, and how many queries each ran against ClickHouse.

VERIFY THE GROUND TRUTH

```
python clickhouse/verify_anomalies.py
```

20 assertions against the live ClickHouse database. Run 7 September 2026: all 20 passed. It checks that the seeded anomalies are present — and that the decoys are too. Households sharing devices, venue devices with high account fan-out and nothing else wrong, a VPN and travel baseline, honest payments carrying rounding drift. Detection here is a discrimination problem, not one equality filter.

```
python -m google.adk.cli eval orchestrator \
  eval/backlot.evalset.json \
  --config_file_path eval/test_config.json
```

5 cases, 23 rubrics generated from ANOMALIES.json. Two of them check that the fleet does NOT invent a finding — an agent that always finds something is worse than useless in operations.

THE ARCHITECTURAL CLAIM, IN ONE LINE

Specialists are attached to the orchestrator with AgentTool, not sub_agents.

In ADK, sub_agents means control TRANSFER: the orchestrator hands the conversation to one specialist and never gets the floor back, so it can never hold two findings at once. Cross-domain correlation is not hard under sub_agents — it is impossible, and no amount of instruction tuning fixes it.

AgentTool returns each finding to the orchestrator, and the same question then produces one synthesized root-cause report. See orchestrator/agent.py.

WHAT RUNS WITH NOBODY IN THE ROOM

Cloud Scheduler calls POST /api/watch/run hourly.

Four standing briefs run against the same orchestrator with no user anywhere in the call stack. The orchestrator triages its own findings into alert / notice / clear and writes them to ClickHouse whether or not anyone has the console open.

Asynchronous in both senses: triggered by a clock rather than a request, and non-blocking — the trigger returns 202 in milliseconds while the investigation keeps running for minutes. See common/watchtower.py.

THE BACKLOT · HOW AN INVESTIGATION RUNS AGENTIC CINEMA · CLICKHOUSE TRACK

01 **TRIGGER**

Two ways in. An operator asks a question — or Cloud Scheduler calls POST /api/watch/run on the hour and nobody is in the room at all.

02 **ROUTE**

Control Room decides which specialists the question actually needs. A single-domain question consults one. It routes; it does not fan out.

03 **DELEGATE, IN ORDER**

premiere_pulse first: name the worst window, with its cdn_node and territory. Then ghost_ads — scoped to that window, not the whole day.

04 **QUERY**

Each specialist writes its own SQL and runs it against ClickHouse Cloud through the official mcp-clickhouse MCP server.

```
WHERE cdn_node = 'sa-east-1b' AND event_time
BETWEEN '19:15' AND '19:30'
```

CLICKHOUSE CLOUD · backlot

05 **RETURN**

AgentTool hands each finding back to the orchestrator. sub_agents would transfer control and never return it — no correlation possible.

06 **CORRELATE**

Two findings sharing a node, a territory and a window are not two incidents. Control Room names the single cause that explains both.

THE RESULT ALERT

CDN node sa-east-1b in Brazil failed between 19:15 and 19:30 UTC, degrading playback and breaking server-side ad insertion at the same time — one cause, two symptoms.

THE WATCHTOWER

Four standing briefs run the same fleet on a Cloud Scheduler clock, with nobody in the room.

Findings are triaged alert / notice / clear and written to ClickHouse whether or not anyone is watching.
